Class and struct and record :

All of them is like blueprint that specifies what the type can do

Class = reference type

Struct = value type

Record = Designed for value-based equality

Some methods and properties are meant to be called or accessed from code outside a class or struct, known as *client code*. Other methods and properties might be only for use in the class or struct itself

You can add the record modifier to a class or a struct

Records are types with built in behavior for value based equality

---

What is indexer ?

You define *indexers* when instances of a class or struct can be indexed like an array or other collection. The indexed value can be set or retrieved without explicitly specifying a type or instance member
